## Diagonalization of Symmetric Real Matrices (from Handout):

Definition 1 Let

$$
\delta_{i j}=\left\{\begin{array}{lll}
1 & \text { if } & i=j \\
0 & \text { if } & i \neq j
\end{array}\right.
$$

A basis $V=\left\{v_{1}, \ldots, v_{n}\right\}$ of $\mathbf{R}^{n}$ is orthonormal if $v_{i} \cdot v_{j}=\delta_{i j}$. In other words, each basis element has unit length, and distinct basis elements are perpendicular.

Observation: Suppose that $x=\sum_{j=1}^{n} \alpha_{j} v_{j}$ where $\left\{v_{1}, \ldots, v_{n}\right\}$ is an orthonormal basis of $V$. Then for any $x \in V$,

$$
\begin{aligned}
x \cdot v_{k} & =\left(\sum_{j=1}^{n} \alpha_{j} v_{j}\right) \cdot v_{k} \\
& =\sum_{j=1}^{n} \alpha_{j}\left(v_{j} \cdot v_{k}\right) \\
& =\sum_{j=1}^{n} \alpha_{j} \delta_{j k} \\
& =\alpha_{k}
\end{aligned}
$$

so

$$
x=\sum_{j=1}^{n}\left(x \cdot v_{j}\right) v_{j}
$$

Example: The standard basis of $\mathbf{R}^{n}$ is orthonormal.

Definition 2 A real $n \times n$ matrix $A$ is unitary if $A^{\top}=A^{-1}$, where $A^{\top}$ denotes the transpose of $A$ : the $(i, j)^{t h}$ entry of $A^{\top}$ is the $(j, i)^{t h}$ entry of $A$.

Theorem $3 A$ real $n \times n$ matrix $A$ is unitary if and only if the columns of $A$ are orthonormal.

Proof: Let $\alpha_{j}$ denote the $j^{\text {th }}$ column of $A$.

$$
\begin{aligned}
A^{\top}=A^{-1} & \Leftrightarrow A^{\top} A=I \\
& \Leftrightarrow \alpha_{i} \cdot \alpha_{j}=\delta_{i j} \\
& \Leftrightarrow\left\{\alpha_{1}, \ldots, \alpha_{n}\right\} \text { is orthonormal }
\end{aligned}
$$

If $A$ is unitary, let $V$ be the set of columns of $A$ and $W$ be the standard basis of $\mathbf{R}^{n}$.
Since $A$ is unitary, it is invertible, so $V$ is a basis of $\mathbf{R}^{n}$.

$$
A^{\top}=A^{-1}=M t x_{V, W}(i d)
$$

Since $V$ is orthonormal, the transformation between bases $W$ and $V$ preserves all geometry, including lengths and angles.

Theorem 4 Let $T \in L\left(\mathbf{R}^{n}, \mathbf{R}^{n}\right)$, W the standard basis of $\mathbf{R}^{n}$. Suppose that $M t x_{W}(T)$ is symmetric. Then the eigenvectors of $T$ are all real, and there is an orthonormal basis $V=\left\{v_{1}, \ldots, v_{n}\right\}$ of $\mathbf{R}^{n}$ consisting of eigenvectors of $T$, so that $\operatorname{Mtx}_{W}(T)$ is diagonalizable:

$$
\begin{aligned}
& \operatorname{Mtx}_{W}(T) \\
& \quad=M t x_{W, V}(i d) \cdot M t x_{V}(T) \cdot M t x_{V, W}(i d)
\end{aligned}
$$

where $M t x_{V} T$ is diagonal and the change of basis matrices $M t x_{V, W}(i d)$ and $M t x_{W, V}(i d)$ are unitary.

The proof of the theorem requires a lengthy digression into the linear algebra of complex vector spaces. Here is a very brief outline.

1. Let $M=M t x_{W}(T)$.
2. The inner product in $\mathbf{C}^{n}$ is defined as follows:

$$
x \cdot y=\sum_{j=1}^{n} x_{j} \cdot \overline{y_{j}}
$$

where $\bar{c}$ denotes the complex conjugate of any $c \in \mathbf{C}$; note that this implies that $x \cdot y=\overline{y \cdot x}$. The usual inner product in $\mathbf{R}^{n}$ is the restriction of this inner product on $\mathbf{C}^{n}$ to $\mathbf{R}^{n}$.
3. Given any complex matrix $A$, define $A^{*}$ to be the matrix whose $(i, j)^{t h}$ entry is $\overline{a_{j i}}$; in other words, $A^{*}$ is formed by taking the complex conjugate of each element of the transpose of $A$. It is easy to verify that given $x, y \in \mathbf{C}^{n}$ and a complex $n \times n$ matrix $A, A x \cdot y=x \cdot A^{*} y$. Since $M$ is real and symmetric, $M^{*}=M$.
4. If $\lambda \in \mathbf{C}$ is an eigenvalue of $M$, with eigenvector $x \in \mathbf{C}^{n}$, then

$$
\begin{aligned}
\lambda|x|^{2} & =\lambda(x \cdot x) \\
& =(\lambda x) \cdot x \\
& =(M x) \cdot x \\
& =x \cdot\left(M^{*} x\right) \\
& =x \cdot(M x) \\
& =x \cdot(\lambda x) \\
& =\overline{(\lambda x) \cdot x} \\
& =\overline{\lambda(x \cdot x)} \\
& =\overline{\lambda|x|^{2}} \\
& =\bar{\lambda}|x|^{2}
\end{aligned}
$$

which proves that $\lambda=\bar{\lambda}$, hence $\lambda \in \mathbf{R}$.
5. If $M$ is real (not necessarily symmetric) and $\lambda \in \mathbf{R}$ is an eigenvalue, then $\operatorname{det}(M-\lambda I)=0 \Rightarrow$ $\exists_{v \in \mathbf{R}^{n}}(M-\lambda I) v=0$, so there is at least one real eigenvector.

Symmetry implies that, if $\lambda$ has multiplicity $m$, there are $m$ independent real eigenvectors corresponding to $\lambda$. Thus, there is a basis of eigenvectors, hence $M$ is diagonalizable over $\mathbf{R}$.
6. Eigenvectors corresponding to distinct eigenvalues are orthogonal: Suppose that $M x=\lambda x$ and $M y=\rho y$ with $\rho \neq \lambda$. Then

$$
\begin{aligned}
\lambda(x \cdot y) & =(\lambda x) \cdot y \\
& =(M x) \cdot y \\
& =(M x)^{\top} y \\
& =\left(x^{\top} M^{\top}\right) y \\
& =\left(x^{\top} M\right) y \\
& =x^{\top}(M y) \\
& =x^{\top}(\rho y) \\
& =x \cdot(\rho y) \\
& =\rho(x \cdot y)
\end{aligned}
$$

so $(\lambda-\rho)(x \cdot y)=0$; since $\lambda-\rho \neq 0$, we must have $x \cdot y=0$.
7. Using the Gram-Schmidt method, we can make the eigenvectors corresponding to a single eigenvalue orthonormal, so we get an orthonormal basis of eigenvectors:

- Suppose we are given independent vectors $x_{1}, \ldots, x_{m} \in \mathbf{R}^{n}$. Let $X=\operatorname{span}\left\{x_{1}, \ldots, x_{m}\right\}$. The Gram-Schmidt method finds an orthonormal basis $\left\{v_{1}, \ldots, v_{m}\right\}$ for $X$.
- Let $v_{1}=\frac{x_{1}}{\left|x_{1}\right|}$. Note that $\left|v_{1}\right|=1$.
- Suppose we have found an orthonormal set $\left\{v_{1}, \ldots, v_{k}\right\}$ such that $\operatorname{span}\left\{v_{1}, \ldots, v_{k}\right\}=\operatorname{span}\left\{x_{1}, \ldots, x_{k}\right\}$, with $k<m$.

Let

$$
y_{k+1}=x_{k+1}-\sum_{j=1}^{k}\left(x_{k+1} \cdot v_{j}\right) v_{j}, v_{k+1}=\frac{y_{k+1}}{\left|y_{k+1}\right|}
$$

$$
\begin{aligned}
\operatorname{span}\left\{v_{1}, \ldots, v_{k+1}\right\} & =\operatorname{span}\left\{v_{1}, \ldots, v_{k}, v_{k+1}\right\} \\
& =\operatorname{span}\left\{v_{1}, \ldots, v_{k}, y_{k+1}\right\} \\
& =\operatorname{span}\left\{v_{1}, \ldots, v_{k}, x_{k+1}\right\} \\
& =\operatorname{span}\left\{x_{1}, \ldots, x_{k}, x_{k+1}\right\}
\end{aligned}
$$

- For $i=1, \ldots, k$,

$$
\begin{aligned}
y_{k+1} \cdot v_{i} & =\left(x_{k+1}-\sum_{j=1}^{k}\left(x_{k+1} \cdot v_{j}\right) v_{j}\right) \cdot v_{i} \\
& =x_{k+1} \cdot v_{i}-\sum_{j=1}^{K}\left(x_{k+1} \cdot v_{j}\right)\left(v_{j} \cdot v_{i}\right) \\
& =x_{k+1} \cdot v_{i}-\sum_{j=1}^{K}\left(x_{k+1} \cdot v_{j}\right) \delta_{i j} \\
& =x_{k+1} \cdot v_{i}-x_{k+1} \cdot v_{i} \\
& =0 \\
& =\frac{0}{\left|y_{k+1}\right|} \\
& =0 \\
v_{k+1} \cdot v_{i} & =\frac{y_{k+1} \cdot v_{i}}{\left|y_{k+1}\right|} \\
\left|v_{k+1}\right| & =\frac{\left|y_{k+1}\right|}{\left|y_{k+1}\right|} \\
& =1
\end{aligned}
$$

## Application to Quadratic Forms

Consider a quadratic form

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n} \alpha_{i i} x_{i}^{2}+\sum_{i<j} \beta_{i j} x_{i} x_{j} \tag{1}
\end{equation*}
$$

Let

$$
\alpha_{i j}= \begin{cases}\frac{\beta_{i j}}{2} & \text { if } i<j \\ \frac{\beta_{j i}}{2} & \text { if } i>j\end{cases}
$$

Let

$$
A=\left(\alpha_{i j}\right) \text { so } f(x)=x^{\top} A x
$$

Example: Let

$$
f(x)=\alpha x_{1}^{2}+\beta x_{1} x_{2}+\gamma x_{2}^{2}
$$

Let

$$
A=\left(\begin{array}{cc}
\alpha & \beta / 2 \\
\beta / 2 & \gamma
\end{array}\right)
$$

so $A$ is symmetric and

$$
\begin{aligned}
& \left(x_{1}, x_{2}\right)\left(\begin{array}{cc}
\alpha & \beta / 2 \\
\beta / 2 & \gamma
\end{array}\right)\binom{x_{1}}{x_{2}} \\
& =\left(x_{1}, x_{2}\right)\binom{\alpha x_{1}+(\beta / 2) x_{2}}{(\beta / 2) x_{1}+\gamma x_{2}} \\
& =\alpha x_{1}^{2}+\beta x_{1} x_{2}+\gamma x_{2}^{2} \\
& =f(x)
\end{aligned}
$$

Return to general quadratic form in Equation (1)
$A$ is symmetric, so let $V=\left\{v_{1}, \ldots, v_{n}\right\}$ be an orthonormal basis of eigenvectors of $A$ with corresponding eigenvalues $\lambda_{1}, \ldots, \lambda_{n}$.

$$
\begin{aligned}
A & =U^{\top} D U \\
D & =\left(\begin{array}{cccc}
\lambda_{1} & 0 & \ldots & 0 \\
& & & \\
0 & \ldots & 0 & \lambda_{n}
\end{array}\right) \\
U & =M t x_{V, W}(i d) \text { is unitary }
\end{aligned}
$$

The columns of $U^{\top}$ (the rows of $U$ ) are the coordinates of $v_{1}, \ldots, v_{n}$, expressed in terms of the standard basis $W$.Given $x \in \mathbf{R}^{n}$, recall

$$
\begin{aligned}
x & =\sum_{i=1}^{n} \gamma_{i} v_{i} \text { where } \gamma_{i}=x \cdot v_{i} \\
f(x) & =f\left(\sum \gamma_{i} v_{i}\right) \\
& =\left(\sum \gamma_{i} v_{i}\right)^{\top} A\left(\sum \gamma_{i} v_{i}\right) \\
& =\left(\sum \gamma_{i} v_{i}\right)^{\top} U^{\top} D U\left(\sum \gamma_{i} v_{i}\right) \\
& =\left(U \sum \gamma_{i} v_{i}\right)^{\top} D\left(U \sum \gamma_{i} v_{i}\right) \\
& =\left(\sum \gamma_{i} U v_{i}\right)^{\top} D\left(\sum \gamma_{i} U v_{i}\right) \\
& =\left(\gamma_{1}, \ldots, \gamma_{n}\right) D\left(\begin{array}{c}
\gamma_{1} \\
\vdots \\
\gamma_{n}
\end{array}\right) \\
& =\sum \lambda_{i} \gamma_{i}^{2}
\end{aligned}
$$

The equation for the level sets of $f$ is

$$
\sum_{i=1}^{n} \lambda_{i} \gamma_{i}^{2}=C
$$

- If $\lambda_{i} \geq 0$ for all $i$, the level set is an ellipsoid, with principal axes in the directions $v_{1}, \ldots, v_{n}$. The length of the principal axis along $v_{i}$ is $\sqrt{C / \lambda_{i}}$ if $C \geq 0$ (if $\lambda_{i}=0$, the level set is a degenerate ellipsoid with principal axis of infinite length in that direction). The level set is empty if $C<0$.
- If $\lambda_{i} \leq 0$ for all $i$, the level is an ellipsoid, with principal axes in the directions $v_{1}, \ldots, v_{n}$. The length of the principal axis along $v_{i}$ is $\sqrt{C / \lambda_{i}}$ if $C \leq 0$ (if $\lambda_{i}=0$, the level set is a degenerate ellipsoid with principal axis of infinite length in that direction). The level set is empty if $C>0$.
$\lambda_{1}>0, \lambda_{2}>0$

- If $\lambda_{i}>0$ for some $i$ and $\lambda_{j}<0$ for some $j$, the level set is a hyperboloid. For example, suppose $n=2, \lambda_{1}>0, \lambda_{2}<0$. The equation is

$$
\begin{aligned}
C & =\lambda_{1} \gamma_{1}^{2}+\lambda_{2} \gamma_{2}^{2} \\
& =\left(\sqrt{\lambda_{1}} \gamma_{1}+\sqrt{\left|\lambda_{2}\right|} \gamma_{2}\right)\left(\sqrt{\lambda_{1}} \gamma_{1}-\sqrt{\left|\lambda_{2}\right|} \gamma_{2}\right)
\end{aligned}
$$

This is a hyperbola with asymptotes

$$
\begin{aligned}
0 & =\sqrt{\lambda_{1}} \gamma_{1}+\sqrt{\left|\lambda_{2}\right|} \gamma_{2} \\
\Rightarrow \gamma_{1} & =-\sqrt{\frac{\left|\lambda_{2}\right|}{\lambda_{1}}} \gamma_{2} \\
0 & =\left(\sqrt{\lambda_{1}} \gamma_{1}-\sqrt{\left|\lambda_{2}\right|} \gamma_{2}\right) \\
\Rightarrow \gamma_{1} & =\sqrt{\frac{\left|\lambda_{2}\right|}{\lambda_{1}}} \gamma_{2}
\end{aligned}
$$

This proves the following corollary of Theorem 4.

Corollary 5 Consider the quadratic form (1).

1. $f$ has a global minimum at 0 if and only if $\lambda_{i} \geq 0$ for all $i$; the level sets of $f$ are ellipsoids with principal axes aligned with the orthonormal eigenvectors $v_{1}, \ldots, v_{n}$.
2. $f$ has a global maximum at 0 if and only if $\lambda_{i} \leq 0$ for all $i$; the level sets of $f$ are ellipsoids with principal axes aligned with the orthonormal eigenvectors $v_{1}, \ldots, v_{n}$.
3. If $\lambda_{i}<0$ for some $i$ and $\lambda_{j}>0$ for some $j$, then $f$ has a saddle point at 0 ; the level sets of $f$ are hyperboloids with principal axes aligned with the orthonormal eigenvectors $v_{1}, \ldots, v_{n}$.

$$
\lambda_{1}>0, \lambda_{2}<0
$$

## Section 3.4: Linear Maps between Normed Spaces

Definition 6 Suppose $X, Y$ are normed spaces, $T \in L(X, Y)$. We say $T$ is bounded if

$$
\exists_{\beta \in \mathbf{R}} \forall_{x \in X}\|T(x)\|_{Y} \leq \beta\|x\|_{X}
$$

Note this implies that $T$ is Lipschitz with constant $\beta$.

Theorem $7(4.1,4.3)$ Let $X, Y$ be normed vector spaces, $T \in L(X, Y)$. Then

$$
\begin{aligned}
& T \text { is continuous at some point } x_{0} \in X \\
& \quad \Leftrightarrow T \text { is continuous at every } x \in X \\
& \quad \Leftrightarrow T \text { is uniformly continuous on } X \\
& \quad \Leftrightarrow T \text { is Lipschitz } \\
& \quad \Leftrightarrow T \text { is bounded }
\end{aligned}
$$

Proof: Suppose $T$ is continuous at $x_{0}$. Fix $\varepsilon>0$. Then there exists $\delta>0$ such that

$$
\left\|z-x_{0}\right\|<\delta \Rightarrow\left\|T(z)-T\left(x_{0}\right)\right\|<\varepsilon
$$

Now suppose $x$ is any element of $X$. If $\|y-x\|<\delta$, let $z=y-x+x_{0}$, so $\left\|z-x_{0}\right\|=\|y-x\|<\delta$.

$$
\begin{aligned}
& \|T(y)-T(x)\| \\
& \quad=\|T(y-x)\| \\
& \left.\quad=\| T\left(y-x+x_{0}-x_{0}\right)\right) \| \\
& \quad=\left\|T(z)-T\left(x_{0}\right)\right\| \\
& \quad<\varepsilon
\end{aligned}
$$

which proves that $T$ is continuous at every $x$, and uniformly continuous.

We claim that $T$ is bounded if and only if $T$ is continuous at 0 . Suppose $T$ is not bounded. Then

$$
\exists_{\left\{x_{n}\right\}}\left\|T\left(x_{n}\right)\right\|>n\left\|x_{n}\right\|
$$

Note that $x_{n} \neq 0$. Let $\varepsilon=1$. Fix $\delta>0$ and choose $n$ such that $\frac{1}{n}<\delta$. Let

$$
\begin{aligned}
x_{n}^{\prime} & =\frac{x_{n}}{n\left\|x_{n}\right\|} \\
\left\|x_{n}^{\prime}\right\| & =\frac{\left\|x_{n}\right\|}{n\left\|x_{n}\right\|} \\
& =\frac{1}{n} \\
& <\delta \\
\left\|T\left(x_{n}^{\prime}\right)-T(0)\right\| & =\left\|T\left(x_{n}^{\prime}\right)\right\| \\
& =\frac{1}{n\left\|x_{n}\right\|}\left\|T\left(x_{n}\right)\right\| \\
& >\frac{n\left\|x_{n}\right\|}{n\left\|x_{n}\right\|} \\
& =1 \\
& =\varepsilon
\end{aligned}
$$

Since this is true for every $\delta, T$ is not continuous at 0 . Therefore, $T$ continuous at 0 implies $T$ is bounded. Now, suppose $T$ is bounded, so find $M$ such that $\|T(x)\| \leq M\|x\|$ for every $x \in X$. Given $\varepsilon>0$, let $\delta=\varepsilon / M$. Then

$$
\begin{aligned}
\|x-0\|<\delta & \Rightarrow\|x\|<\delta \\
& \Rightarrow\|T(x)-T(0)\|=\|T(x)\|<M \delta \\
& \Rightarrow\|T(x)-T(0)\|<\varepsilon
\end{aligned}
$$

so $T$ is continuous at 0 .

Thus, we have shown that continuity at some point $x_{0}$ implies uniform continuity, which implies continuity at every point, which implies $T$ is continuous at 0 , which implies that $T$ is bounded, which implies that $T$ is continuous at 0 , which implies that $T$ is continuous at some $x_{0}$, so all of the statements except possibly the Lipschitz statement are equivalent.

Suppose $T$ is bounded, with constant $M$. Then

$$
\begin{aligned}
\|T(x)-T(y)\| & =\|T(x-y)\| \\
& \leq M\|x-y\|
\end{aligned}
$$

so $T$ is Lipschitz with constant $M$; conversely, if $T$ is Lipschitz with constant $M$, then $T$ is bounded with constant $M$. So all the statements are equivalent.

Theorem 8 (4.5) Let $X, Y$ be normed vector spaces, $T \in L(X, Y)$, $\operatorname{dim} X<\infty$. Then $T$ is bounded.

Proof: See de la Fuente.

Given normed vector spaces $X, Y$, a topological isomorphism between $X$ and $Y$ is a linear transformation $T \in L(X, Y)$ which is invertible (one-to-one, onto), continuous, and has a continuous inverse. Two normed vector spaces $X$ and $Y$ are topologically isomorphic if there is a topological isomorphism $T: X \rightarrow Y$. Suppose $X, Y$ are normed vector spaces. We define

$$
\begin{aligned}
B(X, Y) & =\{T \in L(X, Y): T \text { is bounded }\} \\
\|T\|_{B(X, Y)} & =\sup \left\{\frac{\|T(x)\|_{Y}}{\|x\|_{X}}, x \in X, x \neq 0\right\} \\
& =\sup \left\{\|T(x)\|_{Y}:\|x\|_{X}=1\right\}
\end{aligned}
$$

Theorem 9 (4.8) Let $X, Y$ be normed vector spaces. Then

$$
\left(B(X, Y),\|\cdot\|_{B(X, Y)}\right)
$$

is a normed vector space.

Proof: See de la Fuente.

Theorem 10 (4.9) Let $T \in L\left(\mathbf{R}^{n}, \mathbf{R}^{m}\right)\left(=B\left(\mathbf{R}^{n}, \mathbf{R}^{m}\right)\right)$ ) with matrix $A=\left(a_{i j}\right)$ with respect to the standard bases. Let

$$
M=\max \left\{\left|a_{i j}\right|: 1 \leq i \leq m, 1 \leq j \leq n\right\}
$$

Then

$$
M \leq\|T\| \leq M \sqrt{m n}
$$

Proof: See de la Fuente.

Theorem 11 (4.10) Let $R \in L\left(\mathbf{R}^{m}, \mathbf{R}^{n}\right)$ and $S \in L\left(\mathbf{R}^{n}, \mathbf{R}^{p}\right)$. Then

$$
\|S \circ R\| \leq\|S\|\|R\|
$$

Proof: See de la Fuente.
Define

$$
\Omega\left(\mathbf{R}^{n}\right)=\left\{T \in L\left(\mathbf{R}^{n}, \mathbf{R}^{n}\right): T \text { is invertible }\right\}
$$

Theorem 12 (4.11') Suppose $T \in L\left(\mathbf{R}^{n}, \mathbf{R}^{n}\right)$, E the standard basis of $\mathbf{R}^{n}$. Then

$$
\begin{aligned}
& T \text { is invertible } \\
& \quad \Leftrightarrow \operatorname{ker} T=\{0\} \\
& \quad \Leftrightarrow \operatorname{det}\left(\operatorname{Mtx}_{E}(T)\right) \neq 0 \\
& \quad \Leftrightarrow \operatorname{det}\left(\operatorname{Mtx}_{V, V}(T)\right) \neq 0 \text { for every basis } V \\
& \quad \Leftrightarrow \operatorname{det}\left(\operatorname{Mtx}_{V, W}(T)\right) \neq 0 \text { for every pair of bases } V, W
\end{aligned}
$$

Theorem 13 (4.12) If $S, T \in \Omega\left(\mathbf{R}^{n}\right)$, then $S \circ T \in \Omega\left(\mathbf{R}^{n}\right)$ and

$$
(S \circ T)^{-1}=T^{-1} \circ S^{-1}
$$

Theorem 14 (4.14) Let $S, T \in L\left(\mathbf{R}^{n}, \mathbf{R}^{n}\right)$. If $T$ is invertible and

$$
\|T-S\|<\frac{1}{\left\|T^{-1}\right\|}
$$

then $S$ is invertible. In particular, $\Omega\left(\mathbf{R}^{n}\right)$ is open in $L\left(\mathbf{R}^{n}, \mathbf{R}^{n}\right)=B\left(\mathbf{R}^{n}, \mathbf{R}^{n}\right)$.

Proof: See de la Fuente.

Theorem 15 (4.15) The function $(\cdot)^{-1}: \Omega\left(\mathbf{R}^{n}\right) \rightarrow \Omega\left(\mathbf{R}^{n}\right)$ that assigns $T^{-1}$ to each $T \in \Omega\left(\mathbf{R}^{n}\right)$ is continuous.

Proof: See de la Fuente.
