
Macroeconomics and Search Part I

Richard Rogerson and Robert Shimer

November 8, 2009

Introduction

- lots of existing surveys of search theory
- our paper is a critical assessment of the role of search in macro
- two big issues
 - ▷ business cycles
 - ▷ cross-country

Two Questions

□ is search useful for understanding macroeconomic phenomena?

- ▷ label workers as unemployed
- ▷ descriptive model of individual experiences
- ▷ match a variety of labor market facts
- ▷ focuses our attention on firms' recruiting

□ does search affect model outcomes?

- ▷ gives rise to match-specific rents (Manning)
- ▷ acts like an adjustment cost on labor
- ▷ sectoral shocks lead to time-consuming reallocation
- ▷ frictions create asymmetries in unemployment rate
- ▷ increasing returns in search create multiple equilibria

Past *Handbooks*

“Though search theory is still an active area of research, as this Handbook shows, few economists still look to its mechanisms for much of the explanation of observed fluctuations.”

– Lilien and Hall (1986), *HOLE* vol. 2

Figures

- little fluctuations in labor force over the business cycle
- regularities in labor market flows
 - ▷ much harder to find a job during a recessions
 - ▷ unemployment incidence rises, but less
- matching function is a good description of this data
- the “labor wedge” is countercyclical
 - ▷ as if there is a countercyclical labor income tax
- possible summary: unemployment is caused by drop in job vacancies

Hours, Employment, and Labor Force

Hours, Employment, and Labor Force

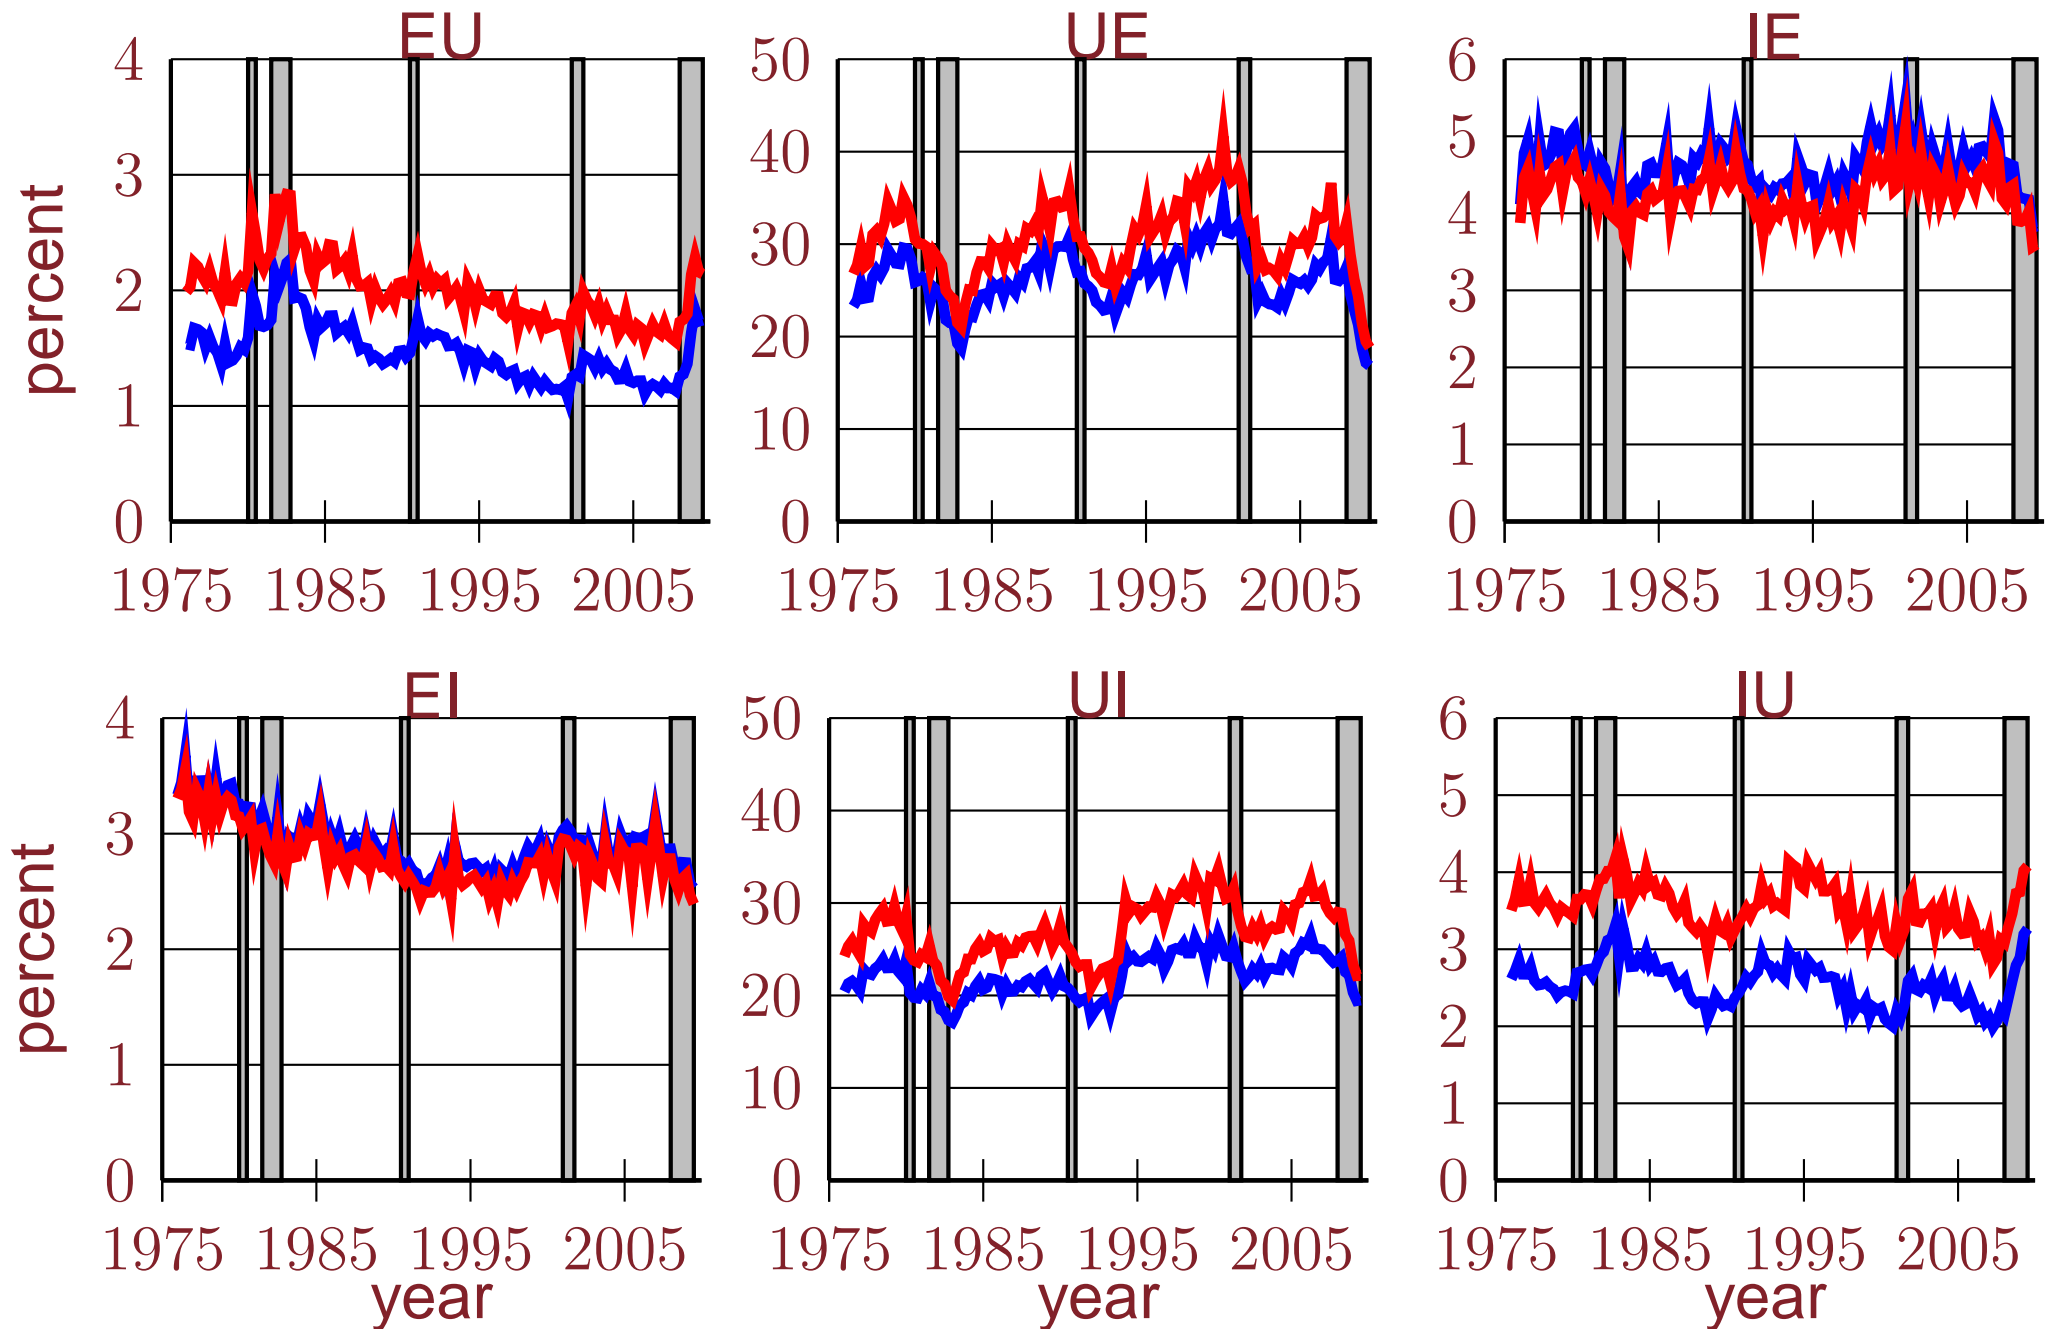

Hours, Employment, and Labor Force

Transition Probabilities

Transition Probabilities

Job Finding Probability

Employment Exit Probability

Employer-to-Employer Transition Probability

Unemployment and Vacancies

Matching Function

$$m_t = m(u_t, v_t), \text{ constant returns}$$

Matching Function

$m_t = m(u_t, v_t)$, constant returns

$$\Rightarrow F_t = m_t/u_t = \mu(v_t/u_t)$$

Matching Function

Labor Wedge

- marginal rate of substitution equals after-tax wage
- marginal product of labor equals wage
- labor market clearing

$$\tau = 1 - \frac{\text{MRS}}{\text{MPL}}$$

Labor Wedge

- marginal rate of substitution equals after-tax wage
- marginal product of labor equals wage
- labor market clearing

$$\tau = 1 - \frac{\text{MRS}}{\text{MPL}}$$

- long-run restrictions pin down MRS and MPL
 - ▷ Cobb-Douglas production function
 - ▷ balanced growth preferences
 - ▷ Frisch labor supply elasticity ε
 - ▷ consumption-labor complementarity is unimportant
- requires only data on hours and consumption/output ratio

Labor Wedge

Labor Wedge

Labor Wedge

Theory

- no unemployment in standard market clearing model
 - ▷ workers choose how much to work

- in a search model, the unemployed cannot find jobs
 - ▷ inelastic labor supply
 - ▷ labor wedge? countercyclical?

- unemployment rises when firms do not create many vacancies
 - ▷ leads to a decrease in the job finding probability

- but why don't firms create vacancies?
 - ▷ requires writing down the model

Sketch of Model

- “standard” neoclassical growth model, except:
- existing workforce is divided between recruiting and production
- recruiters attract new workers, constant returns at firm level
- wages are negotiated via Nash bargaining (match-specific rents)

- details in Shimer, *Labor Markets and Business Cycles* (PUP, 2010)

Resolution of Macro Puzzles?

□ impulses

- ▶ literature focuses on productivity, monetary policy shocks
- ▶ search does not help here at all

□ adjustment cost creates minimal propagation

□ amplification

- ▶ adjustment cost **dampens** employment fluctuations
- ▶ large fluctuations in calibrations that would deliver really large fluctuations without search costs (Hagedorn and Manovskii 2008)

□ theoretical labor wedge is **procyclical**

“Backward-Looking” Wages

- does not really help with impulse mechanisms
- propagates shocks
- amplifies shocks
- pushes towards a countercyclical labor wedge

“Backward-Looking” Wages

- does not really help with impulse mechanisms
- propagates shocks
- amplifies shocks
- pushes towards a countercyclical labor wedge

- but did we need search frictions to do this?
 - ▷ anything that creates match-specific rents frees up wage setting
 - ▷ could even do it without match-specific rents
