## Econ 219B

Psychology and Economics: Applications
(Lecture 3)

Stefano DellaVigna

February 2, 2011

Outline

1. Leisure Goods: Credit Card Borrowing II
2. Leisure Goods: Consumption and Savings I (Life-cycle)
3. Leisure Goods: Consumption and Savings II (Commitments)
4. Methodology: Commitment Field Experiment Designs
5. Methodology: Errors in Applying Present-Biased Preferences
6. Seven More Applications of Present Bias

## 1 Leisure Goods: Credit Card Borrowing II

- Ausubel, "Adverse Selection in Credit Card Market"
- Joint-venture company-researcher
- Field Experiment: Randomized mailing of two million solicitations!
- Follow borrowing behavior for 21 months
- Variation of:
- pre-teaser interest rate $r_{0}: 4.9 \%$ to $7.9 \%$
- post-teaser interest rate $r_{1}$ : Standard - 4\% to Standard $+4 \%$
- Duration of teaser period $T_{s}$ (measured in years)
- Part of the randomization - Incredible sample sizes. How much would this cost to run? Millions

| TABLE 1: SUMMARY OF MARKET EXPERIMENTS |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{gathered} \text { MARKET } \\ \text { EXPERIMENT } \end{gathered}$ | MARKET CELL | NUMBER OF SOLICITATIONS MAILED | EFFECTIVE RESPONSE RATE | $\begin{aligned} & \text { PERCENT } \\ & \text { GOLD } \\ & \text { CARDS } \end{aligned}$ | AVERAGE CREDIT LIMIT |
| MKT EXP I | A: 4.9\% Intro Rate 6 months | 100,000 | 1.073\% | 83.97\% | \$6,446 |
| MKT EXP I | B: 5.9\% Intro Rate 6 months | 100,000 | 0.903\% | 80.18\% | \$6,207 |
| MKT EXP I | C: $6.9 \%$ Intro Rate 6 months | 100,000 | 0.687\% | 80.06\% | \$5,973 |
| MKT EXP I | D: 7.9\% Intro Rate 6 months | 100,000 | 0.645\% | 76.74\% | \$5,827 |
| MKT EXP I | E: 6.9\% Intro Rate 9 months | 100,000 | 0.992\% | 81.15\% | \$6,279 |
| MKT EXP I | F: 7.9\% Intro Rate 12 months | 100,000 | 0.944\% | 82.31\% | \$6,296 |

- Another set of experiments:

| MKT EXP III | A: Post-Intro Rate Standard - 4\% | 100,000 | 1.015\% | 82.96\% | \$5,666 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| MKT EXP III | B: Post-Intro Rate Standard - 2\% | 100,000 | 0.928\% | 77.69\% | \$5,346 |
| MKT EXP III | C: Post-Intro Rate Standard + 0\% | 100,000 | 0.774\% | 76.87\% | \$5,167 |
| MKT EXP III | D: Post-Intro Rate Standard + 2\% | 100,000 | 0.756\% | 76.98\% | \$5,265 |
| MKT EXP III | E: Post-Intro Rate Standard + 4\% | 100,000 | 0.633\% | 73.62\% | \$5,095 |

- Setting:
- Individual has initial credit card $\left(r_{0}^{0}, r_{1}^{0}, T_{s}^{0}\right)$. Balances: $b_{0}$ pre-teaser, $b_{1}$ post-teaser
- Credit card offers: $\left(r_{0}^{\prime}, r_{1}^{\prime}, T_{s}^{\prime}\right)$
- Decision to take-up new credit card:
- switching cost $k>0$
- approx. saving in pre-teaser rates $\left(T_{s}\right.$ years): $T_{s}\left(r_{0}^{\prime}-r_{0}^{0}\right) b_{0}$
- approx. saving in post-teaser rates $\left(21 / 12-T_{s}\right.$ years $)$ : $\left(21 / 12-T_{s}\right)\left(r_{1}^{\prime}-r_{1}\right) b_{1}$
- Net benefit of switching:

$$
N B^{\prime}=-k+T_{s}\left(r_{0}^{\prime}-r_{0}^{0}\right) b_{1}+\left(21 / 12-T_{s}\right)\left(r_{1}^{\prime}-r_{1}^{0}\right) b_{1}
$$

- Switch if $N B+\varepsilon>0$
- Take-up rate $R$ is function of attractiveness $N B$ :

$$
R=R(N B), R^{\prime}>0
$$

- Compare take-up rate of card $i, R^{i}$, to take-up rate of Standard Card $S t$, $R^{S t}$
- Standard Card (6.9\% followed by 16\%) (Card C above)
- Assume $R$ (approximately) linear in a neighborhood of $N B^{S t}$, that is,

$$
R\left(N B^{i}\right)=R\left(N B^{S t}\right)+R_{N B}^{\prime}\left(N B^{i}-N B^{S t}\right)
$$

- Compare cards Pre and $S t$ that differ only in interest rate $r_{0}$ (pre-teaser)
- Assume $b_{0}^{P r e}=b_{0}^{S t}=b_{0}$ (Pre-teaser balance ) $\approx \$ 2,000$
- Difference in attractiveness:

$$
R\left(N B^{P r e}\right)-R\left(N B^{S t}\right)=R_{N B}^{\prime} T_{s}\left(r_{0}^{P r e}-r_{0}^{S t}\right) b_{0}
$$

- Pre-Teaser Offer (Card A): (4.9\% followed by 16\%)
* $N B^{\text {Pre }}-N B^{S t} \approx 6 / 12 * 2 \% * \$ 2,000=\$ 20$
* $R\left(N B^{P r e}\right)-R\left(N B^{S t}\right)=386$ out of 100,000
- Compare cards Post and $S t$ that differ only in interest rate $r_{1}$ (post-teaser)
- Assume $b_{1}^{\text {Post }}=b_{1}^{S t}=b_{1}($ Post-teaser balance $) \approx \$ 1,000$
- Difference in attractiveness:

$$
R\left(N B^{P o s t}\right)-R\left(N B^{S t}\right)=R_{N B}^{\prime}\left(21 / 12-T_{s}\right)\left(r_{1}^{P o s t}-r_{1}^{S t}\right) b_{1}
$$

- Post-Teaser Offer (Card B in Exp. III): (6.9\% followed by 14\%)

$$
* N B^{\text {Post }}-N B^{S t} \approx 15 / 12 * 2 \% * \$ 1000=\$ 25
$$

$$
* R\left(N B^{\text {Post }}\right)-R\left(N B^{S t}\right)=154 \text { out of } 100,000
$$

- Puzzle:
$-N B^{\text {Post }}-N B^{S t}>N B^{\text {Pre }}-N B^{S t}$
- But $R\left(N B^{P r e}\right)-R\left(N B^{S t}\right) \gg R\left(N B^{P o s t}\right)-R\left(N B^{S t}\right)$
- Plot $N B$ and $R(N B)$ for different offers
- Figure 1. Compare offers varying in $r_{0}$ (flat line) and in $r_{1}$ (steep line)

-Post-Intro Interest Rate -Introductory Interest Rate
- Very different slope!
- Figure 2. Vary length of teaser period. Similar findings.

- Introductory Interest Rate - Duration $(6.9 \%$ Intro $) \Longrightarrow$ Duration $(7.9 \%$ Intro $)$
- Figure 1. People underrespond to post-teaser interest rate.
- Why?
- truncation at 21 months?
- (very) high impatience?
- sophistication?
- most plausible: naiveté
- Naive time-inconsistent preferences
- Naives overestimate switching to another card (procrastination)
- Naives underestimate post-teaser borrowing: $\hat{b}_{1}<b_{1}$ and $\hat{b}_{0}=b_{0}$
- Compare cards:

$$
N B^{P r e}-N B^{S t}=T_{s}\left(r_{0}^{P r e}-r_{0}^{S t}\right) b_{0}
$$

and

$$
\widehat{N B}^{P o s t}-\widehat{N B}^{S t}=\left(21 / 12-T_{s}\right)\left(r_{1}^{P o s t}-r_{1}^{S t}\right) \hat{b}_{1}
$$

- Underestimate impact of post-teaser interest rates
- Calibration: $\hat{b}_{1} \approx(1 / 3) b_{1}$
- Figure 2. Variation in $T_{s}$. People underrespond to length of teaser period
- Why?
- Naive agent overestimates probability of switching to another teaser offer

## 2 Leisure Goods: Consumption and Savings I

- Laibson (1997) to Laibson, Repetto, and Tobacman (2007)
- Leisure Good: Temptation to overconsume at present
- Stylized facts:
- Low liquid wealth accumulation
- Extensive credit card borrowing (SCF, Fed, Gross and Souleles 2000)
- Consumption-income excess comovement (Hall and Mishkin, 1982)
- Substantial illiquid wealth (housing+401(k)s)

TABLE 1
SECOND-STAGE MOMENTS

| Description and Name | $\bar{m}_{J_{m}}$ | $\operatorname{se}\left(\bar{m} J_{m}\right)$ |
| :--- | :---: | :---: |
| \% Borrowing on Visa: "\% Visa" | 0.678 | 0.015 |
| Mean (Borrowing $/$ mean(Income t$)$ ): "mean Visa" | 0.117 | 0.009 |
| Consumption-Income Comovement: "CY" | 0.231 | 0.112 |
| Average weighted $\frac{\text { wealth }}{\text { income }: ~ " w e a l t h " ~}$ | 2.60 | 0.13 |

Source: Authors' calculations based on data from the Survey of Consumer Finances, the Federal Reserve, and the Panel Study on Income Dynamics. Calculations pertain to households with heads who have high school diplomas but not college degrees. The variables are defined as follows: \% Visa is the fraction of U.S. households borrowing and paying interest on credit cards (SCF 1995 and 1998); mean Visa is the average amount of credit card debt as a fraction of the mean income for the age group (SCF 1995 and 1998, weighted by Fed aggregates); $C Y$ is the marginal propensity to consume out of anticipated changes in income (PSID 1978-92); and wealth is the weighted average wealth-to-income ratio for households with heads aged 50-59 (SCF 1983-1998).

- Reduced-form evidence here not sufficient
- Life-cycle consumption model (Gourinchas and Parker, 2004)
- Assume realistic features:
- borrowing constraints
- illiquid assets
- bequests...
- Two steps of estimation: of MSM (Method of Simulated Moments)

1. Estimate ('calibrate') auxiliary parameters

- Interest rate
- Mortality
- Income shocks

2. Estimate main parameters $(\beta, \delta)$ using Method of Simulated Moments

-     * Simulate model (cannot solve analytically)
* Choose parameters $(\hat{\beta}, \hat{\delta})$ that minimize distance of simulated moments to estimated moments
* Take into account uncertainty in estimates of 1st stage
- (David Laibson's Slides follow)

## 3 Model

- We use simulation framework
- Institutionally rich environment, e.g., with income uncertainty and liquidity constraints
- Literature pioneered by Carroll $(1992,1997)$, Deaton (1991), and Zeldes (1989)
- Gourinchas and Parker (2001) use method of simulated moments (MSM) to estimate a structural model of life-cycle consumption

### 3.1 Demographics

- Mortality, Retirement (PSID), Dependents (PSID), HS educational group
3.2 Income from transfers and wages
- $Y_{t}=$ after-tax labor and bequest income plus govt transfers (assumed exog., calibrated from PSID)
- $y_{t} \equiv \ln \left(Y_{t}\right)$. During working life:

$$
\begin{equation*}
y_{t}=f^{W}(t)+u_{t}+\nu_{t}^{W} \tag{3}
\end{equation*}
$$

- During retirement:

$$
\begin{equation*}
y_{t}=f^{R}(t)+\nu_{t}^{R} \tag{4}
\end{equation*}
$$

### 3.3 Liquid assets and non-collateralized debt

- $X_{t}+Y_{t}$ represents liquid asset holdings at the beginning of period $t$.
- Credit limit: $X_{t} \geq-\lambda \cdot \bar{Y}_{t}$
- $\lambda=.30$, so average credit limit is approximately $\$ 8,000$ (SCF).

### 3.4 Illiquid assets

- $Z_{t}$ represents illiquid asset holdings at age $t$.
- $Z$ bounded below by zero.
- $Z$ generates consumption flows each period of $\gamma Z$.
- Conceive of $Z$ as having some of the properties of home equity.
- Disallow withdrawals from $Z ; Z$ is perfectly illiquid.
- $Z$ stylized to preserve computational tractability.

### 3.5 Dynamics

- Let $I_{t}^{X}$ and $I_{t}^{Z}$ represent net investment into assets $X$ and $Z$ during period $t$
- Dynamic budget constraints:

$$
\begin{aligned}
X_{t+1} & =R^{X} \cdot\left(X_{t}+I_{t}^{X}\right) \\
Z_{t+1} & =R^{Z} \cdot\left(Z_{t}+I_{t}^{Z}\right) \\
C_{t} & =Y_{t}-I_{t}^{X}-I_{t}^{Z}
\end{aligned}
$$

- Interest rates:

$$
R^{X}=\left\{\begin{array}{lll}
R^{C C} & \text { if } & X_{t}+I_{t}^{X}<0 \\
R & \text { if } & X_{t}+I_{t}^{X}>0
\end{array} ; \quad R^{Z}=1\right.
$$

- Three assumptions for $\left[R^{X}, \gamma, R^{C C}\right]$ :

Benchmark:
Aggressive:
Very Aggressive:
[1.0375, 0.05, 1.1175]
[1.03, 0.06, 1.10]
[1.02, 0.07, 1.09]

In full detail, self $t$ has instantaneous payoff function

$$
u\left(C_{t}, Z_{t}, n_{t}\right)=n_{t} \cdot \frac{\left(\frac{C_{t}+\gamma Z_{t}}{n_{t}}\right)^{1-\rho}-1}{1-\rho}
$$

and continuation payoffs given by:

$$
\begin{aligned}
& \beta \sum_{i=1}^{T+N-t} \delta^{i}\left(\Pi_{j=1}^{i-1} s_{t+j}\right)\left(s_{t+i}\right) \cdot u\left(C_{t+i}, Z_{t+i}, n_{t+i}\right) \ldots \\
& +\beta \sum_{i=1}^{T+N-t} \delta^{i}\left(\Pi_{j=1}^{i-1} s_{t+j}\right)\left(1-s_{t+i}\right) \cdot B\left(X_{t+i}, Z_{t+i}\right)
\end{aligned}
$$

- $n_{t}$ is effective household size: adults+(.4)(kids)
- $\gamma Z_{t}$ represents real after-tax net consumption flow
- $s_{t+1}$ is survival probability
- $B(\cdot)$ represents the payoff in the death state

### 3.7 Computation

- Dynamic problem:

$$
\begin{aligned}
& \max _{I_{t}^{X}, I_{t}^{Z}} \quad u\left(C_{t}, Z_{t}, n_{t}\right)+\beta \delta E_{t} V_{t, t+1}\left(\Lambda_{t+1}\right) \\
& \text { s.t. Budget constraints }
\end{aligned}
$$

- $\wedge_{t}=\left(X_{t}+Y_{t}, Z_{t}, u_{t}\right)$ (state variables)
- Functional Equation:

$$
\begin{aligned}
& V_{t-1, t}\left(\Lambda_{t}\right)= \\
& \left\{s_{t}\left[u\left(C_{t}, Z_{t}, n_{t}\right)+\delta E_{t} V_{t, t+1}\left(\Lambda_{t+1}\right)\right]+\left(1-s_{t}\right) E_{t} B\left(\Lambda_{t}\right)\right\}
\end{aligned}
$$

- Solve for eq strategies using backwards induction
- Simulate behavior
- Calculate descriptive moments of consumer behavior

## 4 Estimation

Estimate parameter vector $\theta$ and evaluate models wrt data.

- $m_{e}=\mathrm{N}$ empirical moments, VCV matrix $=\Omega$
- $m_{s}(\theta)=$ analogous simulated moments
- $q(\theta) \equiv\left(m_{s}(\theta)-m_{e}\right) \Omega^{-1}\left(m_{s}(\theta)-m_{e}\right)^{\prime}$, a scalarvalued loss function
- Minimize loss function: $\hat{\theta}=\arg \min _{\theta} q(\theta)$
- $\hat{\theta}$ is the MSM estimator.
- Pakes and Pollard (1989) prove asymptotic consistency and normality.
- Specification tests: $q(\hat{\theta}) \sim \chi^{2}(N-\#$ parameter $s)$

TABLE 3
BENCHMARK STRUCTURAL ESTIMATION RESULTS

|  | (1) | (2) | (3) | (4) | (5) |
| :---: | :---: | :---: | :---: | :---: | :---: |

Source: Authors' calculations.
Note on standard errors: (i) includes both the first stage correction and the simulation correction, (ii) includes just the first stage correction, (iii) includes just the simulation correction, and (iv) includes neither correction.

TABLE 4
ROBUSTNESS

Figure 1: $q$ versus beta and delta

Figure 1: This figure plots the MSM objective function with respect to beta and delta under the paper's benchmark assumptions. The objective, $q$, equals a weighted sum of squared deviations of the empirical moments from the moments predicted by the model. Lower values of $q$ represent a better fit of the model, and the (beta.delta) pair that minimizes $a$ is the MSM estimator.

## 3 Leisure Goods: Commitments and Savings II

- Ashraf, Karlan, and Yin (2005), QJE
- Different Methodology: Field Experiment
- Different Setting: Philippines
- Three treatments:
- SEED Treatment ( $\mathrm{N}=842$ ): Encourage to save, Offer commitment device (account with savings goal)
- Marketing Treatment ( $\mathrm{N}=466$ ): Encourage to save, Offer no commitment
- Control Treatment ( $\mathrm{N}=469$ )
- Evaluation:
- Compare SEED to Marketing Treatment: Effect of Commitment Device in addition to encouragement
- Measure the effect on total savings (also on non-committed account) - This was not true in 401(k) studies
- SEED Treatment:
- Out of 842 treated people, 202 take up SEED -> Take up of $24 \%$
- 167 also got lock-up box (did not observe savings there)
- Effect of SEED Treatment on Total Savings, Compared to Marketing
- (Remember: Include all 842 people, Intent-to-Treat)
- Share of people with increased Balances: 5.6 percentage (33.3 percent in SEED and 27.7 in Marketing)
- Share of people with increased Balances by at least 20 percent: 6.4 percentage points
- Total Balances: 287 Pesos after 6 months (not significant)
- To compute Treatment-on-The-Treated, divide by 202/842
- Take into account no effect on non-takers (by assumption)

## TABLE VI

Impact on Change in Savings Held at Bank
OLS, Probit

| INTENT TO TREAT EFFECT |  |  |  |  |  |  |  |  |

Robust standard errors in parentheses. * significant at $10 \% ;{ }^{* *}$ significant at $5 \% ;{ }^{* * *}$ significant at $1 \%$. The dependent variable in the first two column is the change in total savings held at the Green Bank after six months. Column (1) regresses chnage in total savings balances on indicators for assignment in the commitment- and marketing-treatment groups. The omitted group indicator in this regression corresponds to the control group. Column (2) shows the regression restricting the sample to commitment- and marketing-treatment groups. Columns (3) and (4) repeat this regression, using change in savings balances after 12 months as a dependent variable. The dependent variable in columns (5)-(8) is a binary variable equal to 1 if balances increased by $\mathrm{x} \%$. 154 clients had pre-intervention a savings balance equal to zero. 24 of them had positive savings after 12 months. These individuals were coded as "one," and those that remain at zero were coded as zero for the outcome variables for columns ( 5 ) through ( 8 ). Exchange rate is 50 pesos for US $\$ 1.00$.

- In addition, examine correlation with a survey response to hyperbolic-discounting-type question:
- Preference between 200 Pesos now and in 1 month
- Preference between 200 Pesos in 6 months and in 7 months

TABLE III
Tabulations of Responses to Hypothetical Time Preference Questions

| Indifferent | Patient | $\mathrm{X}<250$ | Indifferent between 200 pesos in 6 months and X in 7 months |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Patient $X<250$ | $\begin{gathered} \text { Somewhat } \\ \text { Impatient } \\ 250<\mathrm{X}<300 \end{gathered}$ | Most Impatient $300<\mathrm{X}$ | Total |
|  |  |  | $\begin{gathered} 606 \\ 34.4 \% \end{gathered}$ | $\begin{gathered} 126 \\ 7.2 \% \\ \hline \end{gathered}$ | $\begin{array}{r} 73 \\ 4.1 \% \\ \hline \end{array}$ | $\begin{gathered} 805 \\ 45.7 \% \end{gathered}$ |
| between 200 pesos now and | Somewhat <br> Impatient | $250<\mathrm{X}<300$ | $\begin{gathered} 206 \\ 11.7 \% \end{gathered}$ | $\begin{gathered} 146 \\ 8.3 \% \end{gathered}$ | $\begin{gathered} 59 \\ 3.3 \% \end{gathered}$ | $\begin{gathered} 411 \\ 23.3 \% \end{gathered}$ |
| X in one month | Most Impatient | $300<$ X | $\begin{gathered} 154 \\ 8.7 \% \end{gathered}$ | $\begin{gathered} 93 \\ 5.3 \% \\ \hline \end{gathered}$ | $\begin{aligned} & 209 \\ & 17 \% \end{aligned}$ | $\begin{gathered} 546 \\ 31 \% \\ \hline \end{gathered}$ |
|  | Total |  | $\begin{gathered} 966 \\ 54.8 \% \end{gathered}$ | $\begin{gathered} 365 \\ 20.7 \% \end{gathered}$ | $\begin{gathered} 431 \\ 24.5 \% \end{gathered}$ | $\begin{aligned} & 1,762 \\ & 100 \% \end{aligned}$ |

$\square$ "Hyperbolic": More patient over future tradeoffs than current tradeoffs
"Patient Now, Impatient Later": Less patient over future tradeoffs than current tradeoffs.
Time inconsistent (direction of inconsistency depends on answer to open-ended question).

- On average, evidence on hyperbolic-discounting-type preferences
- Interesting idea: Correlate survey response with response to treatment (also in Fehr-Goette paper next lecture)
- Evidence of correlation for women, not for men

## 4 Methodology: Commitment Field Experiment

Designs

- Growing literature on field experiments offering commitment devices
- Recipe:
- Random assignment into treatment and control group
- Treatment group ( $T$ ) offered commitment device (action that imposes constraints)
- Control group (C) is not
- Take-up of commitment is observed in the treatment group
- Outcome (e.g., saving, smoking, eating) observed for both groups
- Three sets of results:

1. Take-up. What share in T use commitment device?

- Smoking gun for time inconsistency, since standard agent would never impose additional constraints
- Time inconsistency can be from present bias, or say from hot/cold states (Bernheim and Rangel 2007)

2. (Who Takes Up? Document who in T takes up commitment)

- Correlation with measured time preferences, previous behavior, etc.
- This is not causal evidence, but still interesting

3. Effect on outcome. Compare outcomes in T and C

- Notice: Here one has to control everybody in T to everybody in C
- Cannot focus on those that took up the commitment in T, since do not know who they compare to in C
- Can rescale effect (Treatment on Treated) by dividing by take-up (under assumption of no effect on no-takers)
- Representative studies: Investment Goods
- Homework Completion (Ariely-Wertenbroch)
- Deadlines are penalties for delivering homework late
- Result 1. Very large take-up rate ( 65 percent)
- Result 3. Large effect on quality of homework and delay (in exp. 2)
- Health-club attendance (Royer and Sydnor, 2010)
- First pay a treatment group to go to the gym
- Then offer half of this treated group commitment device to keep going
- Commitment device is deposit money into an account. money forfeited if do not attend at least once every 14 days for 4 months
- Result 1: Low demand for commitment: 13\% take-up, with average sum of \$63
- Result 3: Some effect on attendance

- Representative studies: Leisure Goods
- Consumption/Savings I (Ashraf-Karlan-Yin)
- Result 1. Commitment device take-up lower (24 percent)
- Result 3. Significant effect on overall savings
- Consumption Savings II (SMRT plan, Thaler and Benartzi, 2007)
- Result 1. Take-up rate $80 \%$ when offered
- Result 3. Huge effects on $401(\mathrm{k})$ contribution rates
- Smoking (Gine, Karlan, and Zinman, 2010)
- Offer urine test for smoking in 6 months
- Can deposit money into account, money forfeited if fail test
- Result 1. Low take-up: 11\%
- Result 3: Increase of 3 percentage point in chance of making urine test
- Result 3: Increase still at surprise test at 12 months
- Online gaming (Chow, 2010 and Acland and Chow, 2010)
- Offer online interface that one can use to limit play of online games
- Result 1. Take-up rate relatively high initially, but declines to 5-10\%
- Result 3. Suggestive effects on time spent playing
- Why often low-take up? At least 3 possibilities:
- Self-control not prevalent
- Self-control prevalent, but naivete' is strong
- Demand for commitment outweighed by costs of commitment in terms of loss of flexibility
- Alternative design of the commiment device field experiments: $2 * 2$ Design (Chow, 2010)
- Offer everyone the commitment device
- Then randomly assign whether commitment device is actually offered
- Therefore groups are 2 (wanted comm./did not) * (got comm./did not)
- Advantage of this design
- More power on demand for commitment since everybody (not just $1 / 2$ of subjects) is asked
- Can estimate effect of commitment both on the subjects that demand it, and the ones who do not (but who may end up using it)

## 5 Methodology: Errors in Applying Present-Biased

## Preferences

- Present-Bias model very successful
- Quick adoption at cost of incorrect applications
- Four common errors
- Error 1. Procrastination with Sophistication
- 'Self-Control leads to Procrastination'
- This is not accurate in two ways
- Issue 1.
* $(\beta, \delta)$ Sophisticates do not delay for long (see our calibration)
* Need Self-control + Naiveté (overconfidence) to get long delay
- Issue 2. (Definitional issue) We distinguished between:
* Delay. Task is not undertaken immediately
* Procrastination. Delay systematically beyond initial expectations
* Sophisticates and exponentials do not procrastinate, they delay
- Error 2. Naives with Yearly Decisions
- 'We obtain similar results for naives and sophisticates in our calibrations'
- Example 1. Fang, Silverman (2007)
- Single mothers applying for welfare. Three states:

1. Work
2. Welfare
3. Home (without welfare)

- Welfare dominates Home - So why so many mothers stay Home?

|  | Choice at $t$ |  |  |
| :--- | :---: | :---: | :---: |
| Choice at $t-1$ | Welfare | Work | Home |
| Welfare |  |  |  |
| Row \% | 84.3 | 3.5 | 12.3 |
| Column \% | 76.7 | 6.3 | 17.9 |
| Work |  |  |  |
| Row \% | 5.3 | 79.3 | 15.3 |
| Column \% | 2.6 | 76.4 | 12.1 |
| Home |  |  |  |
| Row \% | 28.3 | 12.0 | 59.7 |
| Column \% | 20.7 | 17.3 | 70.0 |

-     - Model:
* Immediate cost $\phi$ (stigma, transaction cost) to go into welfare
* For $\phi$ high enough, can explain transition
* Simulate Exponentials, Sophisticates, Naives
- However: Simulate decision at yearly horizon.
- BUT: At yearly horizon naives do not procrastinate:
* Compare:
- Switch now
- Forego one year of benefits and switch next year
- Result:
* Very low estimates of $\beta$
* Very high estimates of switching cost $\phi$
* Naives are same as sophisticates

| Parameters |  | (1) |  | (2) |  | (3) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Time Consistent |  | Present-Biased <br> (sophisticated) |  | Present-Biased (Naive) |  |
|  |  | Estimate | S.E. | Estimate | S.E. | Estimate | S.E. |
| Preference Parameters |  |  |  |  |  |  |  |
| Discount Factors | $\beta$ | 1 | n.a. | 0.33802 | 0.06943 | 0.355 | 0.0983 |
|  | $\delta$ | 0.41488 | 0.07693 | 0.87507 | 0.01603 | 0.868 | 0.02471 |
| Net Stigma | $\phi^{(1)}$ | 7537.04 | 774.81 | 8126.19 | 834.011 | 8277.46 | 950.77 |
| (by type) | $\phi^{(2)}$ | 10100.9 | 1064.83 | 10242.01 | 955.878 | 10350.20 | 1185.27 |
|  | $\phi^{(3)}$ | 13333.2 | 1640.18 | 12697.25 | 1426.40 | 12533.69 | 1685.92 |

-     - Conjecture: If allowed daily or weekly decision, would get:
* Naives fit much better than sophisticates
* $\beta$ much closer to 1
* $\phi$ much smaller
- Example 2. Shui and Ausubel (2005) -> Estimate Ausubel (1999)
* Cost $k$ of switching from credit card to credit card
* Again: Assumption that can switch only every quarter
* Results of estimates (again):
- Quite low $\beta$
- Naives do not do better than sophisticates
- Very high switching costs

Table 4: Estimated Parameters ${ }^{a}$

|  | Sophisticated <br> Hyperbolic | Naive <br> Hyperbolic | Exponential |
| :---: | :---: | :---: | :---: |
| $\beta$ | 0.7863 | 0.8172 |  |
| $\delta$ | $(0.00192)$ | $(0.003)$ |  |
| $k$ | 0.9999 | 0.9999 | 0.9999 |
|  | $(0.00201)$ | $(0.0017)$ | $(0.00272)$ |
| 0.02927 | 0.0326 | 0.1722 |  |
|  | $\$ 293$ | $\$ 326$ | $\$ 1,722$ |
|  | $(0.00127)$ | $(0.00139)$ | $(0.0155)$ |

- Error 3. Present-Bias over Money
- 'We offer the choice between $\$ 10$ today and $\$ 15$ in a week'
- Experiments supporting $(\beta, \delta)$ usually of the above type (Ainslie, 1956; Benhabib, Bisin, and Schotter, 2006; Andreoni and Sprenger, 2009)
- BUT: Discounting applies to consumption, not income (Mulligan, 1999):

$$
U_{0}=u\left(c_{0}\right)+\beta \delta E u\left(c_{1}\right)+\beta \delta^{2} E u\left(c_{2}\right)
$$

- Assume that individual consume the $\$ 10$ in the future $->$ Then the choice is between
* $u(10)$
* $\beta \delta E u(15)$
- Credit constraints $->$ Consume immediately, remove this problem to good extent (but confound with another problem)
- In addition: Uncertainty over future shocks, not in present
- Ideally: Do experiments with goods to be consumed right away:
* Low- and High-brow movies (Read and Loewenstein, 1995)
* Squirts of juice for thirsty subjects (McClure et al., 2005)
- Same problem applies to models
* Notice: Transaction costs of switching $k$ in above models are real effort, apply immediately
* Effort cost $c$ of attending gym also 'real' (not monetary)
* Consumption-Savings models: Utility function of consumption $c$, not income $I$
- Error 4. Getting the Intertemporal Payoff Wrong
- 'Costs are in the present, benefits are in the future'
- $(\beta, \delta)$ models very sensitive to timing of payoffs
- Sometimes, can easily turn investment good into leisure good
- Need to have strong intuition on timing
- Example: Carrillo (1999) on nuclear plants as leisure goods
* Immediate benefits of energy
* Delayed cost to environment
- BUT: 'Immediate' benefits come after 10 years of construction costs!

## 6 Seven More Applications of Present Bias

### 6.1 Fertilizer Adoption

- Duflo, Kremer, and Robinson (2009): Invest in fertilizer
- Development: Why so little adoption of fertilizer and high-yield seeds?
- Literature examining role of learning, social learning
- Effect of fertilizer in Western Kenya
- Field Experiments: In appropriate proportions high returns
- However, low adoption

Table 1: Returns to Fertilizer

|  | Top Dressing 1/4 Teaspoon |  |  | Top Dressing 1/2 Teaspoon |  |  | Top Dressing 1 teaspoon 1 Teaspoon |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Panel A: Not Annualized | mean | median | obs | mean | median | obs | mean | median | obs |
| 25 Ksh per goro-goro | 0.080 | -0.327 | 116 | 0.189 | 0.156 | 202 | -0.476 | -0.494 | 85 |
| 40 Ksh per goro-goro | 0.728 | 0.077 | 116 | 0.903 | 0.850 | 202 | -0.161 | -0.191 | 85 |
| Panel B: Annualized |  |  |  |  |  |  |  |  |  |
| 25 Ksh per goro-goro | 0.362 | -0.794 | 116 | 1.002 | 0.786 | 202 | -0.788 | -0.805 | 85 |
| 40 Ksh per goro-goro | 1.272 | 0.118 | 116 | 1.625 | 1.515 | 202 | -0.190 | -0.225 | 85 |

- Possible explanation of puzzle: Farmers would like to purchase fertilizer, but they run out of money by the time the new season comes
- Experiment (SAFI Program):
- Manipulate timing of adoption
- Farmers can pre-buy fertilizer at end of previous season (when 'rich')
- Significant effect on adoption

Table 8: Adoption for Parents Sampled for School-Based SAFI and Subsidy

| Season | Long Rains 2004 | Short Rains 2004 |
| :--- | :---: | :---: |
| Number of Seasons after School-Based Demonstration Plot | 1 | 2 |
| Number of Seasons after Starter Kit Program | - | 1 |
| Programs for which an effect would be expected in the | SAFI LR 2004 | SAFI SR 04 |
| given season (coefficients in bold) | Demo Plot | Subsidy |
|  |  | Full Price Visit |
|  |  | Starter Kit |
| Panel A. Control for School | $(1)$ | $(2)$ |
| Starter Kit Farmer | 0.085 | 0.047 |
|  | $(0.045)^{*}$ | $(0.049)$ |
| Sampled to Participate in School Demonstration Plot | -0.046 | 0.018 |
|  | $(0.064)$ | $(0.071)$ |
| SAFI Long Rains 2004 | 0.103 | -0.020 |
|  | $(0.038)^{* * *}$ | $(0.043)$ |
| SAFI Short Rains 2004 | -0.037 | 0.169 |
|  | -0.047 | $(0.053)^{* * *}$ |
| Subsidy Short Rains 2004 | -0.046 | 0.142 |
|  | $(0.056)$ | $(0.063)^{* *}$ |
| Full Price Visit Short Rains 2004 | -0.089 | 0.070 |
| Observations | $(0.056)$ | $(0.063)$ |
|  | 874 | 752 |

### 6.2 Job Search

- DellaVigna and Paserman (JOLE 2003)
- Stylized facts:
- time devoted to job search by unemployed workers: 9 hours/week
- search effort predicts exit rates from unemployment better than reservation wage choice
- Model with costly search effort and reservation wage decision:
- search effort - immediate cost, benefits in near future - driven by $\beta$
- reservation wage - long-term payoffs - driven by $\delta$
a

b

- Correlation between measures of impatience (smoking, impatience in interview, vocational clubs) and job search outcomes:
- Impatience $\uparrow \Longrightarrow$ search effort $\downarrow$
- Impatience $\uparrow \Longrightarrow$ reservation wage $\longleftrightarrow$
- Impatience $\uparrow \Longrightarrow$ exit rate from unemployment $\downarrow$
- Impatience captures variation in $\beta$
- Sophisticated or naive - does not matter

Fig. 3.-Exit rates in the NLSY

- Paserman (EJ forthcoming):
- Structural model estimated by max. likelyhood
- Estimation exploits non-stationarity of exit rate from unemployment

### 6.3 Welfare programs

- Fang, Silverman $(2002,2007)$
- Stylized Facts:
- limited transition from welfare to work
- (more importantly) large share of mothers staying home and not claiming benefits
- Examines decisions of single mothers with kids. Three states: Welfare (leisure + benefits), Work (wages), Home (leisure)
- Mothers stay home because of one-time social disapproval of claiming benefits
- Naiveté crucial here

### 6.4 Addiction

- Standard model: Rational addiction (Becker and Murphy, 1988)
- Past consumption lowers current total utility...
- ...but raises current marginal utility
- Stylized facts:
- Diffusion of addictions (drugs, alcohol, tobacco, obesity)
- Repeated efforts of quitters
- Antabuse
- Rational addiction?
- Facts suggestive of present-bias (O'Donoghue and Rabin, 2003; Gruber and Koszegi, 2003)
- Standard test of addiction: Does cigarette consumption at $t$ respond to future prices at $t+1$ ?
- Becker, Grossman, and Murphy, AER 1994: Future prices lower current consumption
- BUT: Data problems (yearly data; sales data, not consumption data)
- Gruber and Koszegi, QJE 2001:
- Response of consumption to present and future taxes at monthly level * Consumption data: Smoking for mothers in National Vital Statistics * Price data: Legislated tax increase at monthly horizon
- Compare response to tax increases at $t+1$ and $t+2$ to estimate $\beta$ and $\delta$
- BUT: limited power $->$ Cannot separate present bias vs. rational addition
- Levy (2009):
- Revisit Gruber and Koszegi, QJE 2001 with novel test for present bias (and projection bias)

1. Compare response to price increase at $t$ and at $t+1$
2. Supplement with response to temporary (price of tobacco) vs. permanent (taxes) price increases

- Some evidence of present bias, stronger evidence of projection bias
- Gruber and Mullainathan (2006): Use happiness data
- (Predicted) smokers happier in states one year after smoking taxes are raised
- Could also be rational response given yearly data

### 6.5 Obesity

- Overweght and obesity rates doubled over last two decades in US:
- 1985: No US state has an obesity rate above 15\%
- 2007: only one state (Colorado) has obesity rate below 20\%, most states are above 25\%
- Problem increasingly common also internationally: UK, Mexico,...
- What explains the increase?
- Cutler, Glaeser, and Shapiro (JEP 2003): Decrease in fixed cost of preparing food + self-control
- Currie, DellaVigna, Moretti, and Pathania (2008): Fast-foods may have a role, but only partial
* Fitness Test for CA 9th graders: Obesity rate increase by 5 percent if f.f. $<.1$ miles of school
* Fitness Test for CA 9th graders: No effect at larger distances
* Weight gain of pregnant mothers: Small (but significant) effect of f.f. $<.5$ miles of residence
* Possible explanation: Self-control problems $->$ Temptation of nearby school
* Could also be transport costs
- Need for field experiments to separate hypotheses

### 6.6 Payday effects

- Shapiro (2003), Melvin (2003), Huffman and Barenstein (2003)
- Stylized facts:
- Purchases increase discretely on payday
- Effect more pronounced for more tempting goods
- Food intake increases as well on payday
- Drug arrests and hospitalization spike on payday (Dobkin and Puller, 2007)
- SSI payments made on 1st of the month

Figure 2: Average Daily Hospital Admissions With Mention of Cocaine, Heroin or Amphetamine By Cash Aide Program (California 1994-2000)

### 6.7 Firm pricing

- T. Two-part tariffs chosen by firms to sell investment and leisure goods (DellaVigna and Malmendier, 2004)
- F. Pricing of magazines (Oster and Scott-Morton, 2005)
- See later Section on Firm Response

### 6.8 Present Bias: Summary

- Present bias/Hyperbolic Discounting
- Reasons for success:

1. Simple model (one-, then two- parameter deviation). YES
2. Powerful intuition (immediate gratification) YES
3. Support in the laboratory OK
4. Support from field data YES

- Lead to new subfield (behavioral contract theory/behavioral IO)
- Next: Reference Dependence
- Status:

1. Simple model (four new features). YES
2. Powerful intuition (reference points) YES
3. Support in the laboratory YES
4. Support from field data OK, more needed
